DB 2

13 - Plan Evaluation

Summer 2020

Torsten Grust Universität Tübingen, Germany

1 Evaluating Query Plan Trees

The evaluation of a (complex) query plan requires a coordinated execution of the plan's operators:

- Is data **pushed** from the leaves (e.g., Seq Scan, Index Scan) towards the plan root?
- Or does an operator **pull** the intermediate results from its upstream child operators?
- What kind of data flows across the plan's edges? Entire tables or columns? Single rows?
- Does the plan execute in one shot or can we **demand** the "next result row" when we are ready to consume it?
 - o Can operators remember/resume from their current state?

Query Q_{12} and its (Moderately Complex) Plan

• **Q**₁₂:

```
SELECT o.a, COUNT(*) AS "#"
FROM one AS o, many AS m
WHERE o.a = m.a
GROUP BY o.a
ORDER BY o.a DESC
```

• Plan operators:

■ Seq Scan on many (outer of 3)
■ Seq Scan on one (inner of 3)
■ Nested Loop (Join Filter: o.a = m.a)

■ HashAggregate (Group Key: o.a)

■ Sort (Sort Key: o.a DESC)

→- ≡ direction of data flow

■ ... ■ evaluation order

many one	a 1 3 3	b A B C	a 1 3	b A B C	а		a 3	# 2 1	
	a 1 1 2 3	b a	3	>-	a 1 3	# 1 2	5	•	

MonetDB: Full Materialization

MonetDB generates MAL programs that evaluate operators following a post-order traversal¹ of the query plan tree.

- Leaf nodes evaluated first, downstream nodes consume BATs generated by child nodes. Root operator evaluated last.
- Each operator consumes entire BATs, generates and **fully** materializes its result BAT(s) [cf. previous slide].
 - Tight code loops process entire columns. Instruction and data locality, predictable memory access.
 - \circ **Size of intermediate results** may exceed available RAM \Rightarrow OS-level paging and thus disk I/O.

 $^{^{1}}$ Recall: data-flow dependency analysis enables the \parallel evaluation of \blacksquare and \blacksquare .

Data Dependencies in MAL Program for Q_{12}

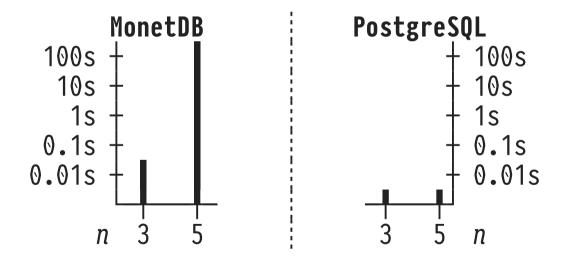

```
:bat[:oid] := sql.tid(sql, "sys", "one");
one
one_a0 :bat[:int] := sql.bind(sql, "sys", "one", "a", 0:int);
                                                                                     ■ Scan one.a
one a :bat[:int] := algebra.projection(one, one a0);
                                                                                         :bat[:oid] := sql.tid(sql| "sys", "many");
many_a0:bat[:int] := sql.bind(sq|, "sys", "many", "a", 0:int);
                                                                                     Scan many.a
many_a :bat[:int] := algebra.pro[ection(many, many_a0);
(left, right) := algebra.join(one_a, many_a, nil:bat, nil:bat, false, nil:lng);
                                                                                      ■ Equi-Join
joined one a:bat[:int] := algebra.projection(left, one a);
(grouped_one_a, group_keys, group_sizes) := group.groupdone(joined_one_a);
keys a:bat[:int] := algebra.projection(group keys, joined one a);

■ Group + Agg
count|:bat[:lng] := aggr.subcount(grouped_one_a, grouped_one_a, group_keys, false);
(sorted_a, oidx, gidx) := algebra.sort(keys_a, true, true, false);
            :bat[:int] := algebra.projection(oidx, keys_a);
                                                                                     Sort
result a
result_count:bat[:lng] := algebra.projection(oidx, count);
```

2 | Materialization vs. Demand-Driven Pipelining

Consider Q_{13} , returning the single value 42:

```
SELECT 42 AS fortytwo FROM hundred AS h_1, ..., hundred AS h_n -- A 100^n rows LIMIT 1
```

Volcano-Style Demand-Driven Pipelining

PostgreSQL implements the Volcano Iterator Model:

- Operator **demands** its subplan to produce the next row (i.e., the plan root drives the query evaluation).
- Operator delivers results **one row at a time**, avoids intermediate result materialization (if possible !):
 - ∘ Reduces query *response* time (first row delivered immediately, do not wait until result is complete). ₺
 - Reduces memory requirements (pass data row-by-row, not table at a time).

Volcano-style **demand-driven** pipelining bears some resemblance with **call-by-need** evaluation of (functional) programming languages:

- If function $f(e_1,e_2)$ does not (always) need the value of expression e_2 , then f(42,1/0) may evaluate just fine.
- With the demand-driven evaluation in Haskell², consider:

```
sum [x/0 \mid x <- [1..10], x > 42] \rightarrow 0.0 length [x/0 \mid x <- [1..10]] \rightarrow 10 take 1 [(x,y) \mid x <- [1..], y <- [1..]] <math>\rightarrow [(1,1)] \bigcirc Q_{13}
```

² Haskell is a *lazily* evaluated functional programming language, see http://haskell.org.

Query Response vs. Evaluation Time

In PostgreSQL's EXPLAIN output, query response (first row) and evaluation time (all rows) are distinguished:

```
Seq Scan on many m (actual time=0.747..139.172 rows=502867 ...)

response/evaluation time
```

- Both times may...
 - ... differ substantially (pipelined evaluation),
 - coincide (blocking operators—e.g., Sort—evaluate in full first, then deliver all rows from intermediate result buffer).

Volcano Iterator Model: API

In Volcano-style demand-driven query evaluation, operators implement a simple API of three main methods:

- open(): Initialize operator and its internal state, forward open() request to upstream subplans as well.
- 2. next(): If required, forward next() upstream to request
 more input rows. Then deliver next output row (or ¼ if
 result complete).
- 3. close(): Release operator-internal state, forward close() request to upstream subplans as well.

Volcano-style call protocol: (open() next()* close())*.

Volcano Iterator Model: Query Evaluation Driver

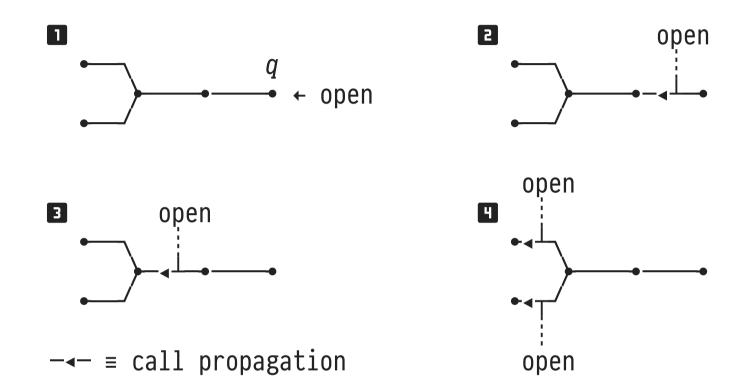

Use the Volcano iterator model API to fully evaluate a query. Operator q denotes the root of the query plan:

- To retrieve next result row only, simply call next(q).
- \bullet May/must use close(q) to cancel query evaluation midway.

Volcano Iterator Model: Forwarding open()/close()

• Each operator instance (→) allocates and releases its own copy of state that is kept between method invocations.

Pipelined Nested Loop Join (NLJ)

Implement open() and close() for the Nested Loop Join
operator:

```
NLJ.close(outer,inner,0):
    close(outer);
    close(inner);
```

Pipelined Nested Loop Join (NLJ, cont'd)

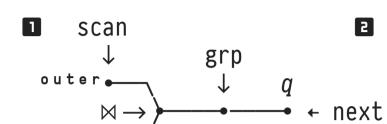

```
NLJ.next(outer,inner,0):
  forever
     if needNewOuter
        o ← next(outer);
                                   } o: current outer row
                                     no more outer rows

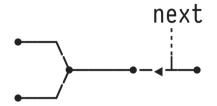

⇒ join complete
        if o = \frac{N}{4}
         L return ∜;
        needNewOuter ← false;
        close(inner);
                                     reset/rescan
                                      inner input
        open(inner);
     i ← next(inner);
                                   } i: current inner row
     if i = \frac{N}{4}
                                     no more inner rows,
      l needNewOuter ← true;
                                      next time: read new outer
     else if o \theta i
                                    join condition satisfied?
              return <0,i>;
                                   } return single joined pair
```

Volcano Iterator Model: Evaluating a NLJ Plan

Volcano Iterator Model: Evaluating a NLJ Plan

Quiz/Exercise: Think about how to implement the following plan operators in the Volcano iterator model:

- Seq Scan (with Filter condition),
- Limit (given a row limit n),
- GroupAggregate (over input sorted by the Group Key),
- Append (SQL: UNION ALL).

Volcano Iterator Model at the SQL Level

Via cursors, the SQL standard exposes the Volcano-style open/next/close API at the level of (Embedded) SQL:

```
-- Generate query plan, no evaluation yet

DECLARE <cursor> [ SCROLL ] CURSOR FOR <query>
-- toursor can move backwards

-- Evaluate plan to deliver the next/prior row (<n> rows)

FETCH [ NEXT | [ FORWARD | BACKWARD ] <n> ] FROM <cursor>

Release plan/intermediate buffers

CLOSE <cursor>
```

Statements need to be issued within an SQL transaction.

Volcano-Style Iteration has its Cost

- Effectively, multiple operators are active at one time.
 - Aggregate intermediate state (memory) may be large.
 - Method call forwarding incurs function call overhead.
 - Frequent switches between code blocks due to row-by-row processing, CPU instruction cache misses are likely.
- © Modern RDBMSs (e.g., VectorWise³, Umbra) seek middle ground between full materialization and pipelining:
 - Build demand-driven pipeline between operators, but...
 - ... pass vectors of rows—typically the size of the CPU's data cache—between operators.
